Emergence and breakdown of linear response in globally coupled systems

Caroline Wormell

Joint work with Georg Gottwald

Setting

Consider family of chaotic systems $x_n = T^{\varepsilon}(x_{n-1})$, with physical measures ρ^{ε} .

The physical measures encode the long-term ergodic behaviour for each T^{ε} . For observables ψ and Lebesgue-a.e. x_0 ,

$$\frac{1}{N}\sum_{n=0}^{N-1}\psi(x_n) \xrightarrow{N\to\infty} \int \psi(x)\,\mathrm{d}\rho^{\varepsilon}(x) =: \mathbb{E}^{\varepsilon}[\psi]$$

$$\mathbb{E}^{arepsilon}[\psi] := \int \psi(x) \, \mathrm{d}
ho^{arepsilon}(x)$$

Linear response theory (LRT) answers: What is $\frac{d}{d\varepsilon} \mathbb{E}^{\varepsilon}[\psi]$? (e.g. for Taylor approximations)

Analytically, we know LRT works in

- Statistical mechanics: Kubo '66
- Stochastic dynamical systems: Hänggi '78, Hairer & Majda '10
- Axiom A (uniformly hyperbolic dissipative chaos): Ruelle '97-8
- Other dissipative systems. . . ?

Analytically, we know LRT works in

- Statistical mechanics: Kubo '66
- Stochastic dynamical systems: Hänggi '78, Hairer & Majda '10
- Axiom A (uniformly hyperbolic dissipative chaos): Ruelle '97-8
- Other dissipative systems...?

Baladi and others ('08, '10, '14, '15) proved there is no linear response for quadratic maps, even Whitney differentiability.

LRT in practice

▲ロ ▶ ▲周 ▶ ▲ ヨ ▶ ▲ ヨ ▶ ● の < ○

Geophysicists have applied LRT to climate systems:

- A long record of success!
- Justified by *chaotic hypothesis*: "macroscopic dynamics are Axiom A"
- However, linear response appears to fail in some systems (e.g. Chekroun *et al.* '14, Cooper and Haynes '13)

Chekroun et al., '14

The question

We address the following question:

When and why does linear response occur at macroscopic scales in high-dimensional dissipative systems?

The question

We address the following question:

When and why does linear response occur at macroscopic scales in high-dimensional dissipative systems?

We study a "simple complex system" of ${\cal M}$ chaotic maps coupled via a mean-field at

- () Infinite size *M* (thermodynamic limit)
- M finite but fairly large

Globally coupled maps

$$q_n^{(j)} = f_{\varepsilon, \Phi_{n-1}}(q_{n-1}^{(j)}), \ j = 1, \dots, M$$

 $\Phi_n = \frac{1}{M} \sum_{j=1}^M \phi(q_n^{(j)})$

Observable is mean field Φ_n .

These systems have rich dynamical and linear response behaviour.

Model reduction

Use exchangeability of subsystems $q^{(j)}$ to write in terms of empirical measure:

$$\mu_n = \frac{1}{M} \sum_{j=1}^M \delta_{q_n^{(j)}}.$$

System becomes

$$\mu_n = f_{\varepsilon, \Phi_n}^* \mu_{n-1}$$
$$\Phi_n = \int \phi \, \mathrm{d}\mu_n$$

Model reduction: thermodynamic limit

In thermodynamic limit $(M \to \infty)$ expect μ_n to be a physical measure of cocycle $\{f_{\varepsilon,\Phi_n}\}_{n\in\mathbb{N}}$:

$$\mu_{n} = \mu_{n}(\Phi_{n-1}, \Phi_{n-2}, \dots; \varepsilon) := \lim_{k \to \infty} f^{*}_{\Phi_{n-1}, \varepsilon} \cdots f^{*}_{\Phi_{n-k}, \varepsilon} \text{Leb}$$

This gives us delay system in Φ :

$$\Phi_n = \int \phi \, \mathrm{d} \mu_n^{\infty} =: F_{\varepsilon}(\Phi_{n-1}, \Phi_{n-2}, \ldots)$$

What are its dynamics?

Model reduction: thermodynamic limit

 Mixing of microscopic dynamics *f* implies *F* only depends on recent history of Φ.
 Macroscopic dynamics are close to finite dimensional!

 For any map g we can find a coupled system with Φ_n ≈ g(Φ_{n-1}).
 All dynamics are possible.

For F to be smooth, we need f to have linear response.

Thermodynamic limit

We studied *f* uniformly expanding (**best possible case** for LRT). We can obtain a period doubling bifurcation to (macroscopic) chaos:

Thermodynamic limit

Despite hyperbolic subsystems, a failure of linear response:

In fact, the macroscopic dynamics are **non-hyperbolic**, contra Gallavotti-Cohen chaotic hypothesis. **Evidence**: homoclinic tangencies.

Finite size

イロト 不得 トイヨト イヨト

-

In climate science have incomplete scale separations: need to consider finite size effects.

Mean-field Φ_n is more or less a random sample from the thermodynamic limit. So by **central limit theorem**,

$$\Phi_n = F_{\varepsilon}(\Phi_{n-1}, \Phi_{n-2}, \ldots) + \frac{1}{\sqrt{M}}\zeta_n,$$

where ζ_n is a mean-zero Gaussian process with decay of correlations etc.

This is a stochastic system.

 \implies we expect LRT

Finite size

Noise induces linear response even when f is nasty (e.g. quadratic map):

▲ロト ▲御ト ▲ヨト ▲ヨト 三回 のへの

Finite size

Likely related to generic distribution of singularities in physical measures (Ruelle '19, W. in progress).

Conclusions

Studied globally coupled systems via models for macroscopic dynamics for large/infinite M.

- Finite size: emergent stochastic effects reliably induce linear response
- In thermodynamic limit need:
 - Microscopic dynamics satisfy LRT
 - Macroscopic dynamics are nice, e.g. hyperbolic (**not** always true)
- Not shown: parameter variation in subsystems helps produce mean-field LRT
- Q: how does this extend to other kinds of couplings?
